A diagram has a defined format that is specific to a particular software tool. A sequence flow is a tree structure of sequence flow elements and is typically constructed by the software tool. The nodes of a sequence flow are called events and the lines that connect the nodes are called arcs. The incoming and outgoing arcs for each event are indicated by an arrow. Each diagram is identified by a unique name. For more information on diagrams see "Universal Automation Diagram Language (UADL) User Guide," Part 1, Version 1.0, November, 1995. UADL is a trademark of the International Foundation for Information Technology (IFIT). "UADL: An IEEE Standard for the Exchange of Combinatorial Information and for the Construction of Diagrams of Software," Publication 1696-1992. For more information on UADL see IFIT, the URL of which is Thus, using a software tool, a sequence flow of events can be created, i.e. a diagram, that indicates how processes are implemented in a software application. Currently, in a software application, code implementing a process is simply copy and pasted and can include a graphic interface on top of a text interface. For example, in a software application that allows a user to connect to a database, the basic logic of connecting to the database is entered into the software application and a graphics menu is provided that allows the user to select the database to be connected to. Thus, in the basic process, the user selects the database, connects to the database and then can perform various functions within the database. When debugging a software application, it is desirable to find the location in the source code of the basic logic of connecting to the database. Unfortunately, there is no simple way to do this. Currently, a user must open the source code of the software application, locate the logic of connecting to the database and then copy and paste that logic into a text editor. This process can be cumbersome and time consuming. In addition, it is difficult for a user to locate the logic of connecting to the database in the source code of the software application, even if the user has a good memory for the code. Thus, there is a need in the art for an efficient and convenient method of viewing and accessing the source code of a software application that enables a user to view and locate the source code of a process.Q: Is there a way to prevent java.io.IO 82157476af
